Lasered Thin

A low-level cool laser, which presents no risk of burning the skin because no heat is involved, is being studied as a noninvasive treatment for excess body fat. The Zerona device (which has FDA approval for other uses) deflates fat cells in targeted areas, releasing the fat into surrounding tissue to be burned off naturally by the body, according to the manufacturer, Erchonia. A clinical trial found that patients treated six times in two weeks, with no changes in diet, lost an average of 0.6 inches with a placebo treatment, says Stephen Shanks, president of Erchonia. “The reported result are intriguing,” says **Brian Biesman**, a former president of the American Society for Laser Medicine and Surgery and an oculoplastic surgeon in Nashville, adding that he looks forward to confirmation with a larger, long-term study reviewed by independent experts.
